

# Reduction of Tree Automata

LC

May 1, 2019

Abstract

## 1 Introduction

## 2 Preliminaries

Let  $\mathbb{N}$  be the set of non-negative integers. A *node* is an element  $u \in \mathbb{N}^*$ . A node  $u$  is a *child* of a node  $v$  if  $u = v \cdot i$  for some  $i \in \mathbb{N}$ . A *tree domain* is a non-empty prefix-closed set of nodes  $D \subseteq \mathbb{N}^*$  s.t., if  $u \cdot (i+1) \in D$ , then  $u \cdot i \in D$  for every  $i \in \mathbb{N}$ . A *leaf* is a node  $u$  in  $D$  without children. A *ranked alphabet* is a family of symbols  $\Sigma = (\Sigma_k)_{k \in \mathbb{N}}$ , where symbols in  $\Sigma_k$  have rank  $k$ . A  $\Sigma$ -*tree* is a function  $t : D \rightarrow \Sigma$ , where  $D$  is a tree domain, s.t., for every node  $u$  in  $D$  labelled with a symbol  $t(u) \in \Sigma_k$  of rank  $k$ ,  $u$  has precisely  $k$  children.

A (finite, nondeterministic, top-down) *tree automaton* is a tuple  $\mathcal{A} = \langle \Sigma, Q, I, \longrightarrow \rangle$  where  $\Sigma$  is a ranked alphabet,  $Q = (Q_k)_{k \in \mathbb{N}}$  is a finite family of states, of which those in  $I \subseteq Q$  are called *initial states*, and  $\longrightarrow = (\xrightarrow{a})_{a \in \Sigma}$  is a finite family of transitions s.t.  $\xrightarrow{a} \subseteq Q_k \times Q^k$  whenever  $a \in \Sigma_k$ . Thus, a state  $q \in Q_k$  only reads symbols of rank  $k$ . Let  $q \in Q$  be a state, and let  $t : D \rightarrow \Sigma$  be an input tree. A *run tree from  $q$  on  $t$*  is a  $Q$ -tree  $r : D \rightarrow Q$  over the same tree domain  $D$  s.t.  $r(\epsilon) = q$  and, for every node  $u \in D$ , if  $t(u) \in \Sigma_k$ , then  $r(u) \xrightarrow{t(u)} r(u \cdot 0) \cdots r(u \cdot (k-1))$ . Whenever such a run tree exists, we write  $q \xrightarrow{t}$ . The *downward language* recognized by a state  $q$ , denoted  $\mathcal{L}^\downarrow(q)$ , is the set of trees  $t$  s.t.  $q \xrightarrow{t}$ . The language recognized by an automaton is  $\mathcal{L}(\mathcal{A}) = \bigcup_{q \in I} \mathcal{L}^\downarrow(q)$ .

A *spine* is a string  $w \in (\bigcup_k \Sigma_k \times \{0, \dots, k-1\} \times Q^{k-1})^*$ . We define  $p \xrightarrow{\epsilon} p$  and  $p \xrightarrow{(a, i, \bar{q}) \cdot w} r$  with  $\bar{q} = q_0 \cdots q_{i-1} q_{i+1} \cdots q_{k-1}$  whenever there exists a transition  $p \xrightarrow{a} q_0 \cdots q_{k-1}$  s.t.  $q_i \xrightarrow{w} r$ .

## 3 Language inclusion

We study preorders which can be used to establish language inclusion.

## 4 Saturation

We study preorders which can be used to add transitions while preserving the language. This can also be used to show that the induced equivalences are GFQ.

*Downward containment transformer*  $\mathcal{T}^\downarrow : 2^{Q \times Q} \mapsto 2^{Q \times Q}$  takes a binary relation on states  $U$ , and yields another binary relation on states  $\mathcal{T}^\downarrow(U)$  s.t., for every states  $p, q \in Q$ ,  $p \mathcal{T}^\downarrow(U) q$  holds if, and only if, for every  $\Sigma$ -tree  $t$  and every  $U$ -jumping  $t$ -run rooted at  $p$ , there exists a  $U$ -jumping  $t$ -run rooted at  $q$ .

*Upward containment transformer*  $\mathcal{T}^\uparrow : 2^{Q \times Q} \times 2^{Q \times Q} \mapsto 2^{Q \times Q}$  takes two binary relation on states  $U$  and  $D$ , and yields another binary relation on states  $\mathcal{T}^\uparrow(U, D)$  s.t., for every states  $p, q \in Q$ ,  $p \mathcal{T}^\uparrow(U, D) q$  holds if, and only if, for every spine  $w = (a_0, i_0, \bar{p}_0) \cdots (a_n, i_n, \bar{p}_n)$  and initial state  $p'$  s.t.  $p' \xrightarrow{w} p$ , there exists a spine  $w' = (a_0, i_0, \bar{q}_0) \cdots (a_n, i_n, \bar{q}_n)$  and an initial state  $q'$  s.t.  $q' \xrightarrow{w'} q$  and  $\bar{p}_j (D \cap U^{-1}) \bar{q}_j$  for every  $0 \leq j \leq n$ .

Let  $\subseteq_0^\downarrow = \subseteq_0^\uparrow = id$ , and, for every  $i \geq 0$ , let

$$\begin{aligned}\subseteq_{i+1}^\downarrow &= \mathcal{T}^\downarrow(\subseteq_i^\uparrow) \\ \subseteq_{i+1}^\uparrow &= \mathcal{T}^\uparrow(\subseteq_i^\uparrow, \subseteq_i^\downarrow)\end{aligned}$$

Finally, define  $\subseteq^\downarrow = \bigcup_i \subseteq_i^\downarrow$  and  $\subseteq^\uparrow = \bigcup_i \subseteq_i^\uparrow$ .
